In the case where we consider the process in a cyclic way like for the animal manure, it's possible to see human excrement as a "resource". By respecting the hygiene requirements, human excrement can easily be composted and turned into pathogens-free humus which doesn't have anything to do with excrement anymore. For the antibiotics (besides significant use), the researches show that there's no durable effect on the composting. It's important to notice that animal manure already used contains at the start the same contaminants including antibiotics.
