Conduits:The smoke exhaust pipe must comply with current standards. These are basic standards and prevent fire from breaking out in the dwelling. There must be a safe distance of 30cm between any wall made of combustible material and a single-skin pipe. A double-skin pipe is to be used for going up inside the roofing and for outside (with a safe distance of 10 cm for it to go through the roofing). A build-up of heat must be avoided at all costs: the 10 cm collar which goes around the pipe where it goes through the roof should not be left unfilled. It will need to be filled with fire-retardant insulation. The temperature could rise sufficiently to catch fire in an empty space (especially if it is closed off from the outside).
